I looked at the plots attached to your message of 08/19.

Figure 2 gives me difficulty because of the extreme slopes for the "weighted line" for blender and cleanup. If this approach is used, I think we have to not use the extrapolated values before the first year and last year of available data. Would it be acceptable to you to keep the value constant before the first and after the last year of available data? Could the same logic be applied to the data in Figure 3?

I will not be in the office on Friday. Can we meet after the US Mag meeting on Monday?

Tim

I will be back from vacation on Thursday, and am wonderinhg if the UC team has had time to debate the pros and cons of the various strategies for modeling concentration vs time in the trionizing department.  
Can we have a calll on Friday to discuss?
